Chapter 5: Link layer

our goals:

- understand principles behind link layer services:
 - error detection, correction
 - sharing a broadcast channel: multiple access
 - link layer addressing
 - local area networks: Ethernet, VLANs
- instantiation, implementation of various link layer technologies

Link layer, LANs: outline

- 5.1 introduction, services 5.5 link virtualization:
- 5.2 error detection, correction
- 5.3 multiple access protocols
- **5.4** LANs
 - addressing, ARP
 - Ethernet
 - switches
 - VLANS

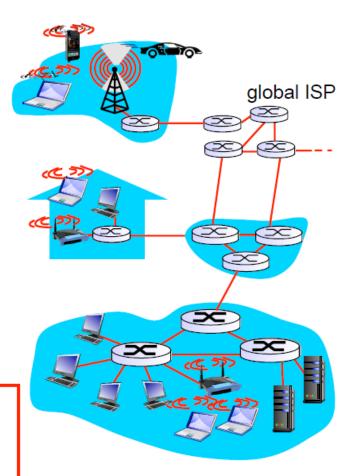

- 5.5 link virtualization MPLS
- 5.6 data center networking
- 5.7 a day in the life of a web request

Link layer: introduction

terminology:

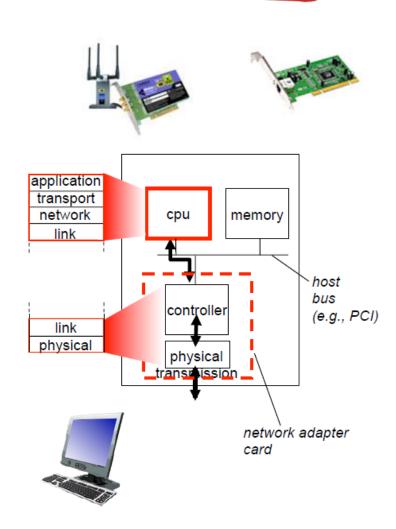

- hosts and routers: nodes
- communication channels that connect adjacent nodes along communication path: links
 - wired links
 - wireless links
 - LANs
- layer-2 packet: frame, encapsulates datagram

data-link layer has responsibility of transferring datagram from one node to physically adjacent node over a link

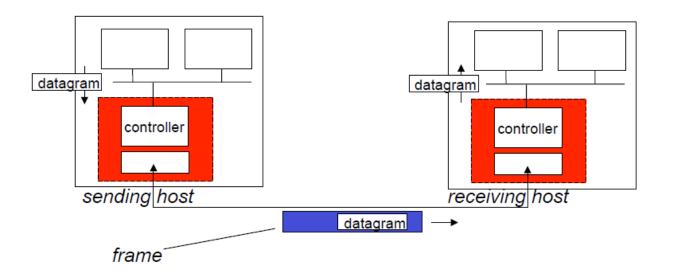

Where is the link layer implemented?

- in each and every host
- link layer implemented in "adaptor" (aka network interface card NIC) or on a chip
 - Ethernet card, 802.11 card; Ethernet chipset
 - implements link, physical layer
- attaches into host's system buses
- combination of hardware, software, firmware

Adaptors communicating

- sending side:
 - encapsulates datagram in frame
 - adds error checking bits, rdt, flow control, etc.

- receiving side
 - looks for errors, rdt, flow control, etc
 - extracts datagram, passes to upper layer at receiving side

Multiple access links, protocols

two types of "links":

- point-to-point
 - PPP for dial-up access
 - point-to-point link between Ethernet switch, host
- broadcast (shared wire or medium)
 - old-fashioned Ethernet
 - upstream HFC
 - 802.11 wireless LAN

shared wire (e.g., cabled Ethernet)

shared RF (e.g., 802.11 WiFi)

shared RF (satellite)

humans at a cocktail party (shared air, acoustical)

An ideal multiple access protocol

given: broadcast channel of rate R bps desire:

- I. when one node wants to transmit, it can send at rate R.
- 2. when M nodes want to transmit, each can send at average rate R/M
- 3. fully decentralized:
 - no special node to coordinate transmissions
 - no synchronization of clocks, slots
- 4. simple

MAC protocols: taxonomy

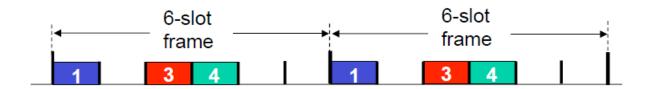

three broad classes:

- channel partitioning
 - divide channel into smaller "pieces" (time slots, frequency, code)
 - allocate piece to node for exclusive use
- random access
 - channel not divided, allow collisions
 - "recover" from collisions
- "taking turns"
 - nodes take turns, but nodes with more to send can take longer turns

Channel partitioning MAC protocols: TDMA

TDMA: time division multiple access

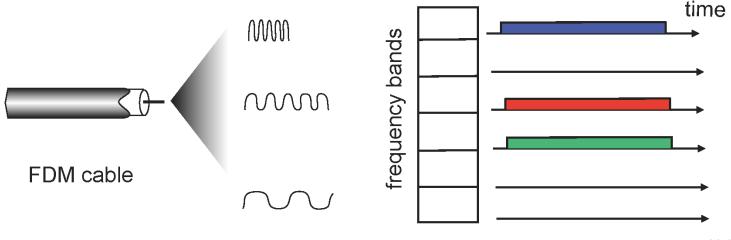

- access to channel in "rounds"
- each station gets fixed length slot (length = pkt trans time) in each round
- unused slots go idle
- example: 6-station LAN, 1,3,4 have pkt, slots 2,5,6 idle

Channel partitioning MAC protocols: FDMA

FDMA: frequency division multiple access

- channel spectrum divided into frequency bands
- each station assigned fixed frequency band
- unused transmission time in frequency bands go idle
- example: 6-station LAN, 1,3,4 have pkt, frequency bands 2,5,6 idle

Random access protocols

- when node has packet to send
 - transmit at full channel data rate R.
 - no *a priori* coordination among nodes
- ❖ two or more transmitting nodes → "collision",
- random access MAC protocol specifies:
 - how to detect collisions
 - how to recover from collisions (e.g., via delayed retransmissions)
- examples of random access MAC protocols:
 - slotted ALOHA
 - ALOHA
 - CSMA, CSMA/CD, CSMA/CA

CSMA (carrier sense multiple access)

CSMA: listen before transmit:

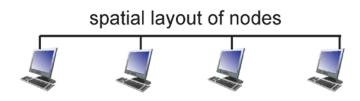

if channel sensed idle: transmit entire frame

if channel sensed busy, defer transmission

human analogy: don't interrupt others!

CSMA collisions

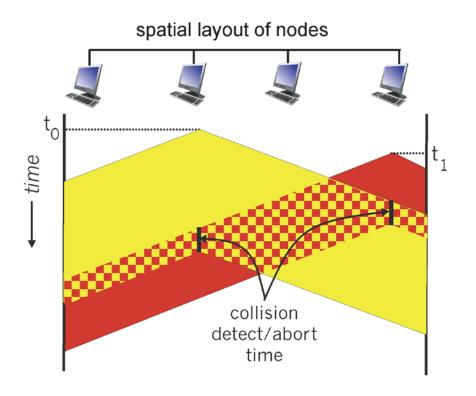

- collisions can still occur: propagation delay means two nodes may not hear each other's transmission
- collision: entire packet transmission time wasted
 - distance & propagation delay play role in in determining collision probability

 t_1

CSMA/CD (collision detection)

Ethernet CSMA/CD algorithm

- I. NIC receives datagram from network layer, creates frame
- 2. If NIC senses channel idle, starts frame transmission. If NIC senses channel busy, waits until channel idle, then transmits.
- 3. If NIC transmits entire frame without detecting another transmission, NIC is done with frame!

- 4. If NIC detects another transmission while transmitting, aborts and sends jam signal
- 5. After aborting, NIC enters binary (exponential) backoff:
 - after mth collision, NIC chooses K at random from {0,1,2,..., 2^m-1}.
 NIC waits K·512 bit times, returns to Step 2
 - longer backoff interval with more collisions

"Taking turns" MAC protocols

channel partitioning MAC protocols:

- share channel efficiently and fairly at high load
- inefficient at low load: delay in channel access, I/N bandwidth allocated even if only I active node!

random access MAC protocols

- efficient at low load: single node can fully utilize channel
- high load: collision overhead

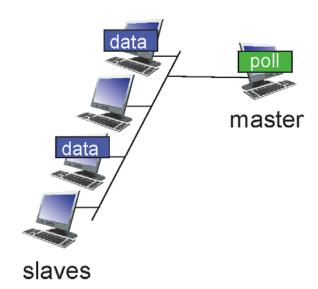

"taking turns" protocols

look for best of both worlds!

"Taking turns" MAC protocols

polling:

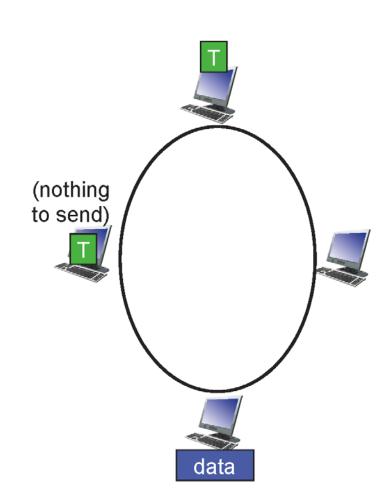

- master node "invites" slave nodes to transmit in turn
- typically used with "dumb" slave devices
- concerns:
 - polling overhead
 - latency
 - single point of failure (master)

"Taking turns" MAC protocols

token passing:

- control token passed from one node to next sequentially.
- token message
- concerns:
 - token overhead
 - latency
 - single point of failure (token)

Summary of MAC protocols

- channel partitioning, by time, frequency or code
 - Time Division, Frequency Division
- random access (dynamic),
 - ALOHA, S-ALOHA, CSMA, CSMA/CD
 - carrier sensing: easy in some technologies (wire), hard in others (wireless)
 - CSMA/CD used in Ethernet
 - CSMA/CA used in 802.11
- taking turns
 - polling from central site, token passing
 - bluetooth, FDDI, token ring
